Abstract

Moringa oleifera presents important medicinal properties, and its seeds are used to treat water for human consumption and wastewater. The aim of the present study was to analyze the initial growth of *M. oleifera* seedlings in enriched commercial substrate with differing doses of controlled release fertilizer. The experimental was designed in randomized blocks, with four repetitions of 16 seedlings each. The treatment used doses of controlled release fertilizer, with 0; 2; 4; 6; and 8 kg m⁻³ of commercial substrate. A hundred days after installing the experiment, the following characteristics were analyzed: height of the aerial part; diameter of the root collar; length; volume; and dry mass of the roots and aerial part. Additionally, the relation between the height of the aerial part and the diameter of the root collar and the Dickson quality index (DQI) were determined. The data was submitted to analysis of variance and to the Shapiro-Wilk test to verify the normality and regression. Controlled release fertilizer at a dose of 5.37 kg m⁻³ of substrate is recommended for *M. oleifera* seedling production.

Keywords: Moringa, fertilizing, propagation, seeds.

Resumo

Fertilizante de liberação controlada no crescimento de mudas de Moringa oleífera Lam. Moringa oleifera apresenta importantes propriedades medicinais e suas sementes são utilizadas no tratamento de água para consumo humano e águas residuais. Objetivou-se neste trabalho analisar o crescimento inicial de mudas de *M. oleifera* em substrato comercial enriquecido com diferentes doses de fertilizante de liberação controlada. O delineamento experimental utilizado foi o em blocos casualizados, com quatro repetições de 16 mudas cada. O tratamento utilizado foram doses de fertilizante de liberação controlada, sendo elas 0; 2; 4; 6 e 8 kg m⁻³ de substrato comercial. Decorridos 100 dias da montagem do experimento, foram analisados: altura da parte aérea; diâmetro do coleto; comprimento; volume; e massa seca de raiz e da parte aérea. Também, foram determinados a relação altura da parte aérea e diâmetro do coleto e o índice de qualidade de Dickson (IQD). Os dados foram submetidos à análise de variância e ao teste de Shapiro-Wilk para verificação da normalidade e regressão. Para a produção de mudas de *M. oleifera*, recomenda-se o fertilizante de liberação controlada na dose de 5,37 kg m⁻³ de substrato.

Palavras-chave: Moringa, adubação, propagação, sementes.

INTRODUCTION

The species *Moringa oleifera* Lam. (Moringaceae) is typical to India and commonly found in tropical and subtropical regions (LEONE *et al.*, 2015). Additionally, it has high nutritional value and excellent medicinal properties,

which has led to it being labelled a miracle tree (GOPALAKRISHNAN *et al.*, 2016). Its leaves are a rich source of nitrogen, calcium, potassium, phosphorous, and vitamins (BASRA *et al.*, 2015), and its seeds are rich in oils, proteins, and fibers (LEONE *et al.*, 2016).

The powder from *M. oleifera* seeds, which has a substance with coagulant properties in its make up that is soluble in water, can be used as a natural coagulant, generating a significant reduction in turbidity and apparent water-color (NDABIGENGESERE *et al.*, 1995; ARANTES *et al.*, 2015). Scarcity of treated water is currently an issue that mainly affects developing countries and drives a search for alternative, cheap and sustainable means to resolve this public health problem (SÁNCHEZ-MARTÍN *et al.*, 2012). Therefore, the use of this plant extract is justified to substitute aluminum sulfate, used as an industrial coagulant in developing countries (SÁNCHEZ-MARTÍN *et al.*, 2012), reducing the cost of water treatment. Other uses of *M. oleifera* seeds reported in the literature include the production of biodiesel (PINTO *et al.*, 2012) and the treatment of water for the dairy industry (VIEIRA *et al.*, 2010).

The success of its cultivation depends directly on the silvicultural procedures adopted, amongst which we find the methods used in seedling production. Consequently, studies to identify substrates that provide the nutrients necessary for the development of quality seedlings are important (CECONI *et al.*, 2007; HE *et al.*, 2016; PACHECO *et al.*, 2016).

Controlled release fertilizers are an interesting alternative, since they provide nutrients for the soil in a gradual manner, making them accessible for plants over an extended period, in comparison with mineral fertilizers. (TIAN *et al.*, 2016). This characteristic allows this type of fertilizer to be applied in greater quantities and less frequently, reduce labor costs in the parcel (TIAN *et al.*, 2016). Additionally, it is being tested for seedling production in nurseries as well as in final plantations (LANG *et al.*, 2011).

Controlled release fertilizers contain granules that are completely covered by a film, normally an elastic polymer. The release of its nutrients occurs through a diffusion process that guarantees its availability in a form adequate for the requirements of the cultures, further minimizing losses resulting from leaching and the damaging effects of salinity (CHEN *et al.*, 2018).

Seedling production employing controlled release fertilizers allows a regulation of the input of nutrients that meets the needs of the plant over time and provides all the substances necessary for their development while still young. This factor contributes to the production of seedlings with greater quality and resistance in the field, given that they are less susceptible to pests and diseases that normally attack debilitated plants (HUBER; JONES, 2013).

Therefore, the objective of the present study is to analyze the initial growth of *M. oleifera* seedlings in commercial substrate enriched with controlled release fertilizer.

MATERIAL AND METHODS

The experiment was conducted in the Forestry Nursery of the Center for Agrarian Sciences and Engineering at the Federal University of Espírito Santo (UFES), situated on the BR 482, municipality of Alegre (state of Espírito Santo, Brazil), and located at the coordinates 20° 45' 02" S and 41° 29' 06" W, at an altitude of 117 m. The climate of the region, according to the Köppen classification, is Cwa, characterized by a dry winter and rainy summer and average annual precipitation of 1,200 mm. The average annual temperature oscillates around 27 °C (INMET, 2015).

M. oleifera obtained from six matrices from the municipality of Iguatu (state of Ceará, Brazil) at the coordinates 6° 13' 12" S and 39° 10' 48" W were used. The climate of the region, according to the Köppen classification, is BSw'h', hot and semiarid, with two well-defined climatic seasons during the year, rainy and dry. The seeds were acclimatized in plastic bags at environmental temperature (25 °C) for 15 days prior to installation of the experiment.

The experimental was designed in randomized blocks, with four repetitions of 16 seedlings each. The treatments consisted of different doses of controlled release fertilizer (CRF): 0; 2; 4; 6 and 8 kg of FLC per m⁻³ of commercial substrate. The chemical composition of the CRF and the commercial substrate is found on Tables 1 and 2, respectively.

OM. Organic material.

The CRF doses were homogenized in the commercial substrate prior to filling the tubes so that all of them received equal amounts of CRF granules, according to the treatment. Sowing was performed at a depth of 0.5 cm in 280 cm³ polypropylene tubes in a shade house with a 50% reduction in light intensity.

Forty days after sowing, the trays containing the seedling in the shade house (50%) were transferred to the rustification area (full sun), leaving an empty cell between one tube and the next. During the experimental period, the seedlings were irrigated daily using a watering can with the quantity of water controlled to reduce nutrient loss from runoff.

A hundred days after sowing, the following parameters were determined: height of the aerial part (H); seedling root collar height up to the apical gem using a cm ruler; diameter of the root collar (CD) measured at the level of the border of the tube using a digital caliper (mm); root length (RL) in cm; root volume (RV) in cm³, obtained using the principal of displaced fluids (Archimedes' Principle); dry mass of the aerial part (DMAP) and root dry mass (RDM), obtained by drying in a fan forced oven at a temperature of 70 °C until constant weight was achieved with subsequent weighing on analytic scales (with a precision of 0.0001 g); ratio of height of aerial part and diameter of the root collar (H/CD); and Dickson quality index (DQI) (DICKSON *et al.*, 1960). The technical maximum efficiency dose (TMED) was calculated for each variable based on the derivatives of the adjusted equations by regression analysis.

The results were analyzed using the Genes program (CRUZ, 2016). Normality of data was verified using the Shapiro-Wilk test at 5% level of significance. After verification of normality, the analysis of variance (ANOVA) was performed as well as regression at 5% probability.

RESULTS

The CRF had a significant effect on the initial growth of *M. oleifera* seedlings in terms of the diameter of the root collar (CD), total dry mass (TDM) dry mass of the aerial part (DMAP), Dickson quality index (DQI), and height of aerial part and diameter of the root collar ratio (H/CD) (Table 3).

Table 3. Analysis of variance of the biometric features and relations studied for *M. oleifera* seedlings in commercial substrate, depending on the FLC dose 100 days after sowing.Tabela 3. Análise de variância das características biométricas e relações estudadas em mudas de *M. oleifera* em substrato comercial em função das doses de FLC após 100 dias da semeadura.

Source of variation	GL	Mean square				
		CD	TDM	DMAP	DQI	H/CD

8	42.928 ± 2.83	18.73 ± 1.92	19.48 ± 2.96	73.36 ± 4.47

Quadratic behavior as a function of CRF doses can be observed for the CD, DMAP, TDM, DQI, and H/DC ratio values (Figures 1A, 1B, 1C, 1D, and 1E, respectively). Quadratic behavior in the variables until reaching the higher CD (7.39 mm), DMAP (43.41 g), TDM (122.86 g), and DQI (18.87) values was observed with increasing CRF doses, with the maximum doses of technical efficiency of CRF (5.98; 6.46; 4.82 and 5.37 kg m⁻³ of substrate respectively).

The lowest values observed for the variables CD, DMAP, TDM and DQI were 5.12 mm, 22.17 g, 103.78 g and 12.85, respectively, in the absence of CRF, which results presenting a difference of 2.27 mm, 21.24 g, 19.08 g, and 6.02 from the doses of technical maximum efficiency (Figure 1). Only the H/DC ratio (7.58) was greater in the absence of CRF (Figure 1E).

Figure 1. Diameter of the root collar – CD (a); dry mass of aerial part – DMAP (b); total dry mass – TDM (c); Dickson quality index – DQI (d); and height of the aerial part and diameter of the root collar ratio – H/CD (e) of *M. oleifera* seedlings in commercial substrate as a function of CRF doses. *: Significant at 5% probability; DTME: Dose of technical maximum efficiency.

Figura 1. Diâmetro do coleto – DC (a), massa seca da parte aérea – MSPA (b), massa seca total – MST (c), índice de qualidade de Dickson – IQD (d), e relação altura da parte aérea e diâmetro do coleto – H/DC (e) de mudas de *M. oleifera* em substrato comercial em função das doses de FLC. *: Significativo a 5% de probabilidade; DMET: Dose de máxima eficiência técnica.

The dose corresponding to the minimum point on the quadratic model for the H/CD ratio (5.91) was 6.49 kg m⁻³ (Figure 1E), indicating the greater hardiness of the seedlings.

DISCUSSION

Morphological parameters provide a clearer understanding of quality and material for the survival potential of forest species seedlings in the field. Some characteristics are understood as predictive of species success, such as the stem diameter and number of leaves for example. These characteristics undergo a significant influence from adequate nutritional management during the seedling production period (PACHECO *et al.*, 2016). It is noted in this study that the use of CRF was influential at the doses tested, generating quadratic models, in which optimal doses for the CD, DMAP, TDM and DQI variables in *M. oleifera* seedlings were found (5.98, 6.46, 4.82, 5.37 kg of CRF per m⁻³ of substrate). Above the optimal dose, there was a reduction in the increase of the growth variables analyzed, leading to phytotoxicity.

The CD, DMAP, TDM and DQI variables presented lower values in the treatment without CRF. When the seedlings received different CRF doses, fertilization generated increases in these variables, as was observed in studies with *Coffea arabica* L., which produced seedlings with greater development and growth when commercial substrate enriched with CRF was used at a concentration of 10 kg m⁻³. This meant that better H/CD, DQI and DMAP values (4.0; 0.21 and 4.7, respectively) were achieved. (MARANA *et al.*, 2008). It was observed therefore, that there was a reduction of seedling diameter growth and total dry mass, caused by an absence of fertilizer. This result showed the importance of this fertilization for the formation of *M. oleifera* seedlings given that it promoted an increase in their vigor, which implied their adaptation to the field and consequently in success for the propagation of the species.

According to Vieira *et al.* (2008), N and K are the macronutrients that most accumulate in *M. oleifera* seedlings, followed by Ca, S, P and Mg. They are probably responsible for the growth of the aerial part and the root system in the *M. oleifera* seedlings in the present study. Studies with other controlled release fertilizers have also been conducted, for example with the formulations 14-14-14 and 15-9-12, which positively influenced the species *Anadenanthera colubrina* (Veloso) (BRONDANI *et al.*, 2008) and *Coffea arabica* L., respectively, in the variables H, DMAP, CD, and TDM (MARANA *et al.*, 2008). A lack of N most affects dry mass production, followed by absences of P, Mg and S (VIEIRA *et al.*, 2007). This indicates that nutritional levels are important for the formation of quality seedlings and in contributing to dry mass accumulation.

A higher CD indicates a higher chance of survival for the seedling when placed into the field (DELARMELINA *et al.*, 2014). A value of 6.1 mm for CD was observed for *M. oleifera* seedlings cultivated in Red-Yellow Latosols with sandy texture evaluated 60 days after sowing (OLIVEIRA *et al.*, 2013).

A higher H/CD ratio (7.58) was obtained in the absence of CRF. This occurred because the height variable (H) was not significantly influenced by the CRF doses, different from the diameter, which presented quadratic behavior. This meant that the curve of the H/CD ratio maintained the same standard as the CD, however with opposed concavity. A similar result was observed by Brondani *et al.* (2018) for *Anadenanthera colubrina*. The authors found the values of the ratio between 7.1 and 7.6 when testing doses between 0 and 4 kg m⁻³ of the CRF formulation 14-14-14, respectively. However, the control obtained the lower value.

For *Araucaria angustifolia* (Bert.) O. Ktze. seedlings, the use of CRF provided values between 6.13 and 8.73 for the H/CD ratio, with doses of 6 and 9 kg m⁻³, respectively. When evaluating the initial growth of *Ocotea odorifera* (Vellozo) Rohwer with the same doses, Rossa *et al.* (2011) observed values between 5.43 and 6.39 in this order. These studies indicate that there is variability in this ratio depending on the species studied, the type of CRF and the time for total nutrient release.

The CRF dose that lead to the highest DQI value (18.87) was 5.37 kg m⁻³ of substrate, different to the control treatment without addition of fertilizer, in which a lower index (12.85) was obtained. Therefore, this indicates that CRF promotes an increase in seedling quality.

CONCLUSION

- For the production of *Moringa oleifera* seedlings, controlled release fertilizer at a dose of 5.37 kg m⁻³ of substrate is recommended, due to its presenting higher DQI.
